Flask with External Web APIs

« Back to Homepage

- Client-side requests (via AJAX) • Server-side requests **Why Use Client-Side Requests?**
- Where Do You Get API Keys? How Do You Use API Keys?
- **Keeping Your Secrets** Example External APIs and Flask
- How External APIs Get Used in Flask
- **API Libraries** API Libraries
- Can be faster: browser could talk directly to, say, Google Maps **Keeping Your Secrets Why Use Server-Side Requests?**
- You can do easily using AJAX libraries Don't have to involve Flask in the API

Flask with External Web APIs

Download Demo Code

**API Requests** 

Browser

Two ways to talk with APIs:

request

response

AJAX request

AJAX response

```
External API
                                              request
            request
                           Flask Server
                                             response
Browser
           response
                                                               Your DB
```

Flask Server

External API

- Same-Origin Policy may prevent browser requests • Easier for server to store/process the data
- e.g. have Flask requests restaurants and store in SQL database Need password to access API
- If API uses password & we make request in browser JS, people could learn password from reading JS

Your DB

Springboard

### \$ curl -i

**iTunes API** 

```
'https://itunes.apple.com/search?term=billy+bragg&limit=3'
  "resultCount":5,
  "results": [
   {"wrapperType":"track", "kind":"song", "artistId":"163251",
iTunes API Help
```

Returns JSON responses

**Python Requests** 

requests.get(url, params)

```
(venv) $ pip install requests
```

## **GET Requests**

```
import requests
resp = requests.get(
            "https://itunes.apple.com/search",
            params={"term": "billy bragg", "limit": 3}
print(resp.json())
```

#### requests.post(url, data, json) data

**POST Requests** 

```
Dictionary of data to send in traditional web from format
```

json Dictionary of data to send as a JSON string Most modern APIs expect to receive JSON, not traditional web form format.

Responses Both .get() and .post() return a Response instance

#### .status\_code

.text

Text of response

```
Numeric status code (200, 404, etc)
.json()
   Convert JSON response text to Python dictionary
API Keys/Secrets
```

#### Many APIs require "keys" and "secrets" (similar to a "username" and "password")

Why Do They Need API Keys?

• The API provides access to confidential data or sensitive methods

### Only you should be able to send tweets from your Twitter account

- The API costs money to use They need to know who to charge
- They want to limit abuse

Google Maps is free, but they want to keep you to from abusing it

- Where Do You Get API Keys?
- Typically: you register on their site. The process is different for every site.
- Example: YouTube API Key

```
API key created
How Do You Use API Keys?
```

### It varies by different APIs For example, if this API needed a secret key sent with requests, they might expect as a URL parameter:

requests.get("http://some-api.com/search",

params={"key": "dhf489tuhdfhdskfsdfsd34tg", "isbn": "4675436632"})

```
Or, they might need complex encoding — varies by API!
Read the API docs!
```

### What's the potential problem? app.py

**Keeping Your Secrets** 

from flask import Flask API\_SECRET\_KEY = "jdfghfkgdg9345dkjfgdfg"

Import that file into your app.py

Don't check that file into Git!

```
app = Flask(__name__)
You'll want to store this file in Git — and probably GitHub
You don't want the world to learn your API key!
Strategy: store the key info in a small, separate file
```

#### secrets.py API\_SECRET\_KEY = "jdfghfkgdg9345dkjfgdfg" арр.ру

Example

```
from flask import Flask
 from secrets import API_SECRET_KEY
 app = Flask(__name__)
.gitignore
 secrets.py
Make sure it never gets into your Git!
 $ git status
 # Should NOT show up here at all
 $ git add .
 $ git status
```

# \$ git commit ...

**External APIs and Flask** 

# Should NOT show up here at all

request Flask Server Browser

**How External APIs Get Used in Flask** 

```
HTML
app.py
```

Sometimes Flask gets JSON data and it returns HTML:

```
@app.route("/book-info")
 def show_book_info():
     """Return page about book."""
     isbn = request.args["isbn"]
     resp = requests.get("http://some-book-api.com/search",
         params={"isbn": isbn, "key": API_SECRET_KEY})
     book_data = resp.json()
     # using the APIs JSON data, render full HTML page
     return render_template("book_info.html", book=book_data)
Sometimes Flask gets JSON data and JSON data to front end:
```

External API

Your DB

External API

request

**JSON** 

Browser

AJAX request

**JSON** 

```
Your DB
app.py
 @app.route("/book-data")
 def show_book_info():
     """Return info about book."""
     isbn = request.args["isbn"]
     resp = requests.get("http://some-book-api.com/search",
```

Flask Server

params={"isbn": isbn, "key": API\_SECRET\_KEY}) book\_data = resp.json() # using the APIs JSON data, return that to browser return jsonify(book\_data) This is helpful if you can't make request info directly from browser — because of Same-Origin-Policy or need to

keep key/secret out of browser

request

**JSON** 

### **API Libraries** Some popular APIs have specialized libraries (sometimes known as SDKs) written for a specific programming

**Python-Twitter** 

language that can help out. For example, there is a Python library for calling the Twitter API:
